

Question

Write a Java program to demonstrate the handling of `NumberFormatException` using try-catch.

Steps for Execution

1. Create a package named `javapractice`.
2. Create a Java class named `NumberException`.
3. Declare a String variable `str` and assign "Hello" to it.
4. Enter the try block.
5. Display "Converting string into number".
6. Use `Integer.parseInt(str)` to convert the String into an integer.
7. Since "Hello" is not a valid number, Java throws `NumberFormatException`.
8. The catch block catches the exception.
9. Display "String cannot be converted into a number".
10. Stop the program.

Algorithm

1. **Start**
2. Declare a String variable `str`.
3. Assign "Hello" to `str`.
4. Start the try block.
5. Convert `str` into an integer using `Integer.parseInt()`.
6. If the String cannot be converted, catch `NumberFormatException`.
7. Display the appropriate error message.
8. **Stop**

UML Class Diagram

Code

```
package javapractice;
```

```
public class NumberException {  
    public static void main(String[] args) {  
        String str = "Hello";  
  
        try {  
            System.out.println("Converting string into number");  
            int n = Integer.parseInt(str);  
            System.out.println(n);  
        }  
        catch (NumberFormatException e) {  
            System.out.println("String cannot be converted into a number");  
        }  
    }  
}
```

Output

```
Converting string into number
```

String cannot be converted into a number

Result

The program successfully demonstrates `NumberFormatException` handling using a try-catch block. The exception occurs because the String "Hello" cannot be converted into an integer.
