

Question

Write a Java program to demonstrate the handling of NullPointerException using try-catch.

Steps for Execution

1. Create a package named javapractice.
2. Create a Java class named NullException.
3. Declare a String variable and assign null to it.
4. Enter the try block.
5. Display "Finding string length".
6. Try to find the length of the null string using str.length().
7. Since str contains null, Java throws a NullPointerException.
8. The catch block catches the exception.
9. Display "String value is null".
10. Stop the program.

Algorithm

1. **Start**
2. Declare a String variable str.
3. Assign null to str.
4. Start the try block.
5. Print "Finding string length".
6. Find the length of str.
7. If str is null, catch NullPointerException.
8. Print "String value is null".
9. **Stop**

UML Class Diagram

Code

```
package javapractice;

public class NullException {

    public static void main(String[] args) {

        String str = null;

        try {

            System.out.println("Finding string length");

            System.out.println(str.length());

        }

        catch (NullPointerException e) {

            System.out.println("String value is null");

        }

    }

}
```

Output

```
Finding string length
String value is null
```

Result

The program successfully demonstrates `NullPointerException` handling using a try-catch block. The exception occurs because `length()` is called on a null `String` reference.
